Beta-blockade in the management of systolic dysfunction
Jonathan A. Abbott, DVM

In the September 2004 issue (Volume 34, number 5), on page 1166, the second line reads, “Based on pharmacodynamic studies of healthy dogs [74], an initial carvedilol dose of about 0.1 mg/kg seems reasonable and appears to be generally well tolerated by dogs with myocardial dysfunction.”

The sentence should read:
“The initial carvedilol dose that is optimal with respect to patient tolerance is not known, but based on pharmacodynamic studies performed in healthy dogs, a starting dose less than 0.1 mg/kg is probably reasonable. Possibly, very large dogs should receive proportionately lower doses, and it might be prudent to use initial doses that are no greater than 3.125 mg PO q 12h regardless of the patient’s body weight.”
